

A new ergodic proof of a theorem of W. Veech

Panagiotis Georgopoulos

Abstract. Our goal in the present paper is to give a new ergodic proof of a well-known Veech’s result, build upon our previous works [4,5].

Keywords: Invariant measure · Skew product · Uniformly distributed sequence · Uniquely ergodic and non-sensitive action · amenable group · Bernoulli shift.

Mathematics Subject Classification (2010) Primary 28D15, 37B05, 43A07; Secondary 11K06.

1 Introduction

W. Veech in his remarkable paper [11, Theorem 3] (see also [7, p. 235] and [8, Commentary of Problem 116, p. 203]), proved the following:

“Almost all” sequences $(r_1, \dots, r_n, \dots)$ of positive integers have the following “universal” property: Whenever G is a compact separable group and $z_1, z_2, \dots, z_n, \dots$ a sequence of elements of G that generates a dense subgroup of G , then the sequence $y_1, y_2, \dots, y_n, \dots$, where $y_n := z_{r_1} \cdot z_{r_2} \dots z_{r_n}$ is uniformly distributed for the Haar measure on G . Veech called such sequences, “uniformly distributed sequence generators”.

In [5] we prove that:

P. Georgopoulos

Department of Mathematics, University of Athens, 15784, Athens, Greece
email: pangeorgopoul@gmail.com & pgeorgop@math.uoa.gr

“Almost all” sequences $(r_1, \dots, r_n, \dots)$ of positive integers have the following “universal” property: Whenever (X, μ) is a Borel probability measure, compact metric space and $\Phi_1, \Phi_2, \dots, \Phi_n, \dots$ a sequence of continuous, measure preserving maps on (X, μ) , such that the action (by composition) on (X, μ) of the semigroup with generators $\Phi_1, \dots, \Phi_n, \dots$ is amenable (as discrete), uniquely ergodic and non-sensitive on $\text{supp}\mu$, then for every $x \in X$ the sequence $w_1, w_2, \dots, w_n, \dots$ where

$$w_n := \Phi_{r_n}(\Phi_{r_{n-1}}(\dots(\Phi_{r_2}(\Phi_{r_1}(x)))\dots))$$

is uniformly distributed for μ .

In the present paper we prove the next most special, albeit not direct, corollary of [5].

“Almost all” sequences $(r_1, \dots, r_n, \dots)$ of positive integers have the following “universal” property: Whenever G is a locally compact, amenable, separable group acting (continuously) on (X, μ) (a Borel probability measure compact metric space), by measure preserving homeomorphisms, such that the action is uniquely ergodic for μ and non-sensitive on $\text{supp}\mu$ (it turns out that such an action is necessarily equicontinuous) and if $\Phi_n, n \in \mathbb{N}$ is a sequence in G that generates (by composition) a dense semigroup in G and $x \in X$, then the sequence $w_n := \Phi_{r_n}(\Phi_{r_{n-1}}(\dots(\Phi_{r_2}(\Phi_{r_1}(x)))\dots)), n \in \mathbb{N}$ is uniformly distributed for μ .

This completes investigation of [4,5] and gives Veech’s theorem, at least for metrizable groups.

The new element in the present paper is Proposition 4.1 that allows us to use a combination of the methods of [4,5]. In fact, in many aspects, most parts of the arguments of [4,5] are much simpler.

Next, let us explain how Veech’s theorem falls in the frame of the above result.

Clearly, G acts on G (uniformly equicontinuously) by multiplication, i.e.

for $g \in G$, $x \in G$, $(x, g) \mapsto x \cdot g$, G is amenable (as compact) and the Haar measure m_G is the unique invariant measure for this action. Also, the assumption that $z_1, z_2, \dots, z_n, \dots$ generate a dense subgroup of G , implies that the action of this subgroup on G (by right translations) is uniquely ergodic for m_G .

On the other hand, the assumption that $z_1, z_2, \dots, z_n, \dots$ generate a dense subgroup of G , is equivalent to the assumption that $z_1, z_2, \dots, z_n, \dots$ generate a dense semigroup in G (see [6, Theorem 9.16]).

Under these circumstances for G metrizable, in view of our result (in particular for $x = e$) the sequence $y_n := z_{r_1} \cdot z_{r_1} \dots z_{r_n}$, $n \in \mathbb{N}$ is uniformly distributed for G .

And a final remark: The general case, where the group G is not necessarily metrizable, can be treated by similar methods, since the topology of G is defined by a family of pseudometrics (see [3, Chapter IX, Section 11]).

2 The main results

Throughout this paper $(p_1, \dots, p_n, \dots)$ is a probability sequence with non-zero entries (i.e. $p_n > 0$ for each n and $\sum_{n=1}^{\infty} p_n = 1$). We consider now the set of natural numbers $\mathbb{N} = \{1, 2, \dots\}$ endowed with the discrete topology. Then, we take the one-point compactification of $\mathbb{N}$ and we get the compact space $\tilde{\mathbb{N}} := \mathbb{N} \cup \{\infty\}$. Let $(\tilde{\mathbb{N}}, m)$ be the measure space, where m is a probability measure on $\tilde{\mathbb{N}}$, defined by $m(\{n\}) = p_n$, for every point n on $\mathbb{N}$ and $m(\{\infty\}) = 0$. On the space $Y := \tilde{\mathbb{N}}^{\mathbb{Z}}$, $\mathbb{Z}$ the integers, we consider the product measure $\lambda := \prod_{n=-\infty}^{+\infty} m$ and the two-sided Bernoulli shift $T: Y \rightarrow Y$, with $T(\{x_n\}) = \{y_n\}$, where $y_n = x_{n+1}$, for every $n \in \mathbb{Z}$.

Also, throughout this paper, G is an amenable, locally compact separable group acting (continuously) on a Borel probability measure, compact metric space (X, μ) and the action is uniquely ergodic for μ and non-sensitive on

$\text{supp}\mu$. It turns out (see Corollary 4.1), that such an action is necessarily equicontinuous.

Next, let $\Phi_1, \dots, \Phi_n, \dots$ be a sequence in G , that generates a dense semigroup in G . (Note that the action of this semigroup in (X, μ) is also uniquely ergodic).

We set up the skew product

$$\Psi : X \times Y \rightarrow X \times Y \text{ defined by } \Psi(x, r) := (\Phi_{r_1}(x), T(r))$$

where $r := (\dots, r_{-n}, \dots, r_{-1}, r_0, r_1, \dots, r_n, \dots)$, conventionally we set

$$\Phi_\infty \equiv Id_X \text{ (} Id_X \text{ the identity on } X \text{)}.$$

Clearly Ψ is Borel measurable and $\mu \times \lambda$ is invariant under Ψ .

Theorem 2.1. *If τ is a Borel probability measure on $X \times Y$, invariant for Ψ , such that the projection of τ on Y equals λ , then τ coincides with $\mu \times \lambda$.*

From the above theorem, taking $r = (\dots, r_{-n}, \dots, r_{-1}, r_0, r_1, \dots, r_n, \dots) \in \mathbb{N}^{\mathbb{Z}}$ a generic point for T , it is easily seen, using some standard results (see [5, pp. 193-194]), that $(r_1, \dots, r_n, \dots)$ has the property mentioned in the abstract.

3 Invariant measures for continuous maps

The space $M(X)$ of all Borel probability measures on X is metrizable in the weak* topology. If $\{f_n\}_{n=1}^\infty$ is a dense subset of $C(X)$ (the space of continuous functions on X), then

$$d(\sigma, \nu) := \sum_{n=1}^{\infty} \frac{|\int f_n d\sigma - \int f_n d\nu|}{2^n \|f_n\|}$$

is a metric on $M(X)$ giving the weak* topology. Also, $M(X)$ is compact in this topology.

For $\Phi : X \rightarrow X$ continuous, hence Borel measurable, we have the continuous affine map

$$\varphi : M(X) \rightarrow M(X) \text{ given by } (\varphi\sigma)(B) = \sigma(\Phi^{-1}(B))$$

for B a Borel set.

We have

Theorem 3.1. *Let F_m , $m \in \mathbb{N}$ be a Følner sequence in G . For $\nu \in M(X)$ and $m \in \mathbb{N}$ we consider the measures*

$$\mu_m^\nu := \frac{1}{m_G(F_m)} \int_{F_m} \varphi(\nu) dm_G(\Phi)$$

(where m_G is the Haar measure on G), or more concretely

$$\int_X f(x) d\mu_m^\nu(x) := \frac{1}{m_G(F_m)} \int_{F_m} \int_X f(\Phi(x)) d\nu(x) dm_G(\Phi)$$

for every $f \in C(X)$ and every $m \in \mathbb{N}$.

Then, $d(\mu_m^\nu, \mu) \rightarrow 0$ for $m \rightarrow \infty$ uniformly for $\nu \in M(X)$.

Proof. Suppose that the conclusion of the theorem does not hold. Then, there exist an $\varepsilon > 0$, a subsequence F_{m_n} , $n \in \mathbb{N}$ of F_m , $m \in \mathbb{N}$ and a sequence ν_n , $n \in \mathbb{N}$ in $M(X)$ such that

$$d(\mu_{m_n}^{\nu_n}, \mu) > \varepsilon. \tag{1}$$

For $f \in C(X)$ we have

$$\int_X f(x) d\mu_{m_n}^{\nu_n}(x) := \frac{1}{m_G(F_{m_n})} \int_{F_{m_n}} \int_X f(\Phi(x)) d\nu_n(x) dm_G(\Phi)$$

and for $H \in G$ ($h : M(X) \rightarrow M(X)$ the induced map),

$$\begin{aligned} \int_X f(x) dh(\mu_{m_n}^{\nu_n}(x)) &:= \frac{1}{m_G(F_{m_n})} \int_{F_{m_n}} \int_X f(H \circ \Phi(x)) d\nu_n(x) dm_G(\Phi) \\ &= \frac{1}{m_G(F_{m_n})} \int_{H F_{m_n}} \int_X f(\Phi(x)) d\nu_n(x) dm_G(\Phi). \end{aligned}$$

So

$$\begin{aligned}
& \left| \int_X f(x) d\mu_{m_n}^{\nu_n}(x) - \int_X f(x) dh(\mu_{m_n}^{\nu_n}(x)) \right| \\
& \leq \frac{1}{m_G(F_{m_n})} \int_{F_{m_n} \triangle HF_{m_n}} \int_X |f(\Phi(x))| d\nu_n(x) dm_G(\Phi) \\
& \leq \frac{m_G(F_{m_n} \triangle HF_{m_n})}{m_G(F_{m_n})} \|f\|_\infty \rightarrow 0 \text{ for } n \rightarrow \infty.
\end{aligned}$$

Hence, every w^* -limit of the sequence $\mu_{m_n}^{\nu_n}$, $n \in \mathbb{N}$ is invariant under the action of G , so equals μ contradicting (1). $\square$

4 Some results on amenable, non-sensitive actions

We recall the following

Definition 4.1. (See also [1, p. 23]) A continuous action of a group G , on a compact metric space (X, v) (v denotes the metric on X), is called sensitive on a subset $X' \subset X$, if there exists a $\beta > 0$, such that for every $x \in X'$ and $\delta > 0$, there exist a $y \in X$ with $v(x, y) < \delta$ and an $h \in G$, such that $v(h(x), h(y)) \geq \beta$. Otherwise the action is called non-sensitive on $X' \subset X$.

We set for $k \in \mathbb{N}$

$$\begin{aligned}
E_k &:= \{x \in X : \text{there exists an open neighborhood } U \text{ of } x \text{ such that} \\
& \quad x_1, x_2 \in U \Rightarrow v(\Phi(x_1), \Phi(x_2)) < \frac{1}{k}, \text{ for all } \Phi \in G\}.
\end{aligned}$$

Clearly, E_k is open and since the action of G is non-sensitive on $\text{supp}\mu$, $E_k \cap \text{supp}\mu \neq \emptyset$, for every $k \in \mathbb{N}$.

Note that a $x \in X$ is an equicontinuity point for G , if for every $\varepsilon > 0$ there exists a $\delta > 0$ such that $v(x, y) < \delta$ implies $v(\Phi(x), \Phi(y)) < \varepsilon$, for every $\Phi \in G$. Clearly, $\bigcap_{k=1}^{\infty} E_k$ is the set of equicontinuity points for G .

Lemma 4.1. Let $k \in \mathbb{N}$. Then for every $x \in X \setminus E_k$ there exists a $\Phi_{i_x} \in G$, such that $\Phi_{i_x}(x) \in E_k$.

Proof. For $k \in \mathbb{N}$, the set

$$Q_k := (X \setminus E_k) \setminus \bigcup_{\Phi \in G} \Phi^{-1}(E_k)$$

is compact and forward invariant under the elements of G .

In case that $Q_k \neq \emptyset$, by an application of Day's fixed point theorem [2, Theorem 1], there exists a Borel probability measure τ supported on Q_k and invariant under G , so $\tau = \mu$. But this contradicts the fact that $E_k \cap \text{supp} \mu \neq \emptyset$, for every k . So, $Q_k = \emptyset$ and the conclusion of the lemma follows immediately. $\square$

Corollary 4.1. *The group G acts on X equicontinuously.*

Proof. Since the maps $\Phi : X \rightarrow X$, $\Phi \in G$ are open (as homeomorphisms), it is easily seen that $\Phi(E_k) \subseteq E_k$ for every $k \in \mathbb{N}$ and $\Phi \in G$.

Let $x \in X$. Suppose, if possible, that x is not an equicontinuity point for the action of G in X . Then

$$x \in X \setminus \bigcap_{k=1}^{\infty} E_k.$$

So, there exists a $k_0 \in \mathbb{N}$ such that $x \notin E_{k_0}$. By the previous lemma, there exists a $\Phi_{i_x} \in G$ such that $\Phi_{i_x}(x) \in E_{k_0}$. Since $\Phi(E_{k_0}) \subseteq E_{k_0}$, for every $\Phi \in G$, clearly we have $\Phi_{i_x}^{-1} \circ \Phi_{i_x}(x) = x \in E_{k_0}$, a contradiction. $\square$

We set $Seq := \bigcup_{n=1}^{\infty} \mathbb{N}^n$ the set of finite sequences of positive integers, and for $r = (r_1, \dots, r_n) \in Seq$, $\Phi_r := \Phi_{r_n} \circ \dots \circ \Phi_{r_1}$, $\varphi_r := \varphi_{r_n} \circ \dots \circ \varphi_{r_1}$ and $\Theta := \{\varphi_r : r \in Seq\}$.

Under the above setting we have the following proposition, which is the new element that gives the possibility to use a combination of the methods of [4,5] in the present situation (see [5, Proposition 3.1]).

Proposition 4.1. *There exists a sequence ρ_m , $m \in \mathbb{N}$ in $\text{conv}(\Theta)$ (the convex hull of Θ) such that*

$$d(\rho_m(\sigma), \mu) \rightarrow 0 \quad \text{uniformly for } \sigma \in M(X).$$

Proof. By Theorem 3.1, we can assume that there exist a Følner sequence F_m , $m \in \mathbb{N}$ in G , and $\varepsilon_m > 0$, $m \in \mathbb{N}$ with $\varepsilon_m \rightarrow 0$ for $m \rightarrow \infty$ such that setting, for $\sigma \in M(X)$, $\mu_m^\sigma \in M(X)$ with

$$\int_X f d\mu_m^\sigma := \frac{1}{m_G(F_m)} \int_{F_m} \int_X f(\Phi(x)) d\sigma dm_G(\Phi) \quad \text{for } f \in C(X)$$

we have

$$d(\mu_m^\sigma, \mu) < \varepsilon_m \quad \text{for } m = 1, 2, \dots \quad \text{and } \sigma \in M(X). \quad (2)$$

Let $D \subseteq X$ be denumerable, with $\overline{D} = X$. We enumerate $D = \{x_i : i \in \mathbb{N}\}$ and set $A := \{\delta_{x_i} : x_i \in D, i \in \mathbb{N} \text{ and } \delta_{x_i} \text{ is the Dirac measure on } x_i\}$ ($\subseteq M(X)$).

Also, let $\{f_n : n \in \mathbb{N}\} (\subseteq C(X))$ be dense in $C(X)$ (clearly $\{f_n : n \in \mathbb{N}\}$ defines the metric on $M(X)$, see above).

Let $m \in \mathbb{N}$. For $n = 1, \dots, m$, $i = 1, \dots, m$ we set

$$g_n^i : G \rightarrow \mathbb{R}, \quad \text{where } g_n^i(\Phi) = \int_X f_n \circ \Phi(x) d\delta_{x_i}.$$

It is easily seen, that the above g_n^i are continuous.

Clearly, for $m \in \mathbb{N}$ and $n = 1, \dots, m$, $i = 1, \dots, m$ we have

$$\int_X f_n d\mu_m^{\delta_{x_i}} = \frac{1}{m_G(F_m)} \int_{F_m} g_n^i(\Phi) dm_G. \quad (3)$$

We set $B := \{\Phi_\ell : \ell \in \text{Seq}\}$. By assumption we have $\overline{B} = G$.

By [9, Chapter II, Theorem 6.3], for $m \in \mathbb{N}$ there exists a convex combination

$$\sum_{k=1}^{k_m} \lambda_k \delta_{\Phi_{\ell_k}}, \quad \Phi_{\ell_k} \in B, \quad k = 1, \dots, k_m$$

of Dirac measures on $M(G)$, such that for $i = 1, \dots, m$ and $n = 1, \dots, m$

$$\left| \frac{1}{m_G(F_m)} \int_{F_m} g_n^i(\Phi) dm_G - \sum_{k=1}^{k_m} \lambda_k g_n^i(\Phi_{\ell_k}) \right| \leq \varepsilon_m \cdot \|f_n\|.$$

So, in view of (3) and the definition of the g_n^i 's, for $m \in \mathbb{N}$, $i = 1, \dots, m$ and $n = 1, \dots, m$

$$\left| \int_X f_n d\mu_m^{\delta_{x_i}} - \sum_{k=1}^{k_m} \lambda_k \int_X f_n \circ \Phi_{\ell_k}(y) d\delta_{x_i} \right| \leq \varepsilon_m \cdot \|f_n\|. \quad (4)$$

Setting $\rho_m := \sum_{k=1}^{k_m} \lambda_k \varphi_{\ell_k}$, we have for $m \in \mathbb{N}$, $i = 1, \dots, m$ and $n = 1, \dots, m$

$$\left| \int_X f_n d\mu_m^{\delta_{x_i}} - \int_X f_n d\rho_m(\delta_{x_i}) \right| \leq \varepsilon_m \cdot \|f_n\|.$$

So, for $m \in \mathbb{N}$ and $i = 1, \dots, m$

$$\begin{aligned} d(\mu_m^{\delta_{x_i}}, \rho_m(\delta_{x_i})) &\leq \varepsilon_m \left(1 - \frac{1}{2^m}\right) + 2 \sum_{n=m+1}^{\infty} \frac{1}{2^n} \\ &< \varepsilon_m + \frac{1}{2^{m-1}}. \end{aligned} \quad (5)$$

Combining (2) and (5), it follows that for $m \in \mathbb{N}$ and $i = 1, \dots, m$

$$d(\rho_m(\delta_{x_i}), \mu) < 2\varepsilon_m + \frac{1}{2^{m-1}}. \quad (6)$$

Claim 1. $\rho_m(\delta_x) \rightarrow \mu$ uniformly for $x \in X$.

Let $\varepsilon > 0$. There exists an $m_0 \in \mathbb{N}$ such that

$$\frac{1}{2^{m-1}} < \varepsilon \quad \text{and} \quad \varepsilon_m < \varepsilon \quad \text{for} \quad m > m_0.$$

Let $f_1, \dots, f_{m_0}$. For the given $\varepsilon > 0$ there exists $\delta > 0$, such that for $x, x' \in X$ with $v(x, x') < \delta$

$$|f_n(x) - f_n(x')| < \varepsilon \cdot \|f_n\| \quad \text{for} \quad n = 1, \dots, m_0$$

(where v denotes the metric on X).

Since $B := \{\Phi_\ell : \ell \in Seq\}$ is equicontinuous, for the above $\delta > 0$ there exists $\theta > 0$ such that for $y, y' \in X$ with $v(y, y') < \theta$

$$v(\Phi_\ell(y), \Phi_\ell(y')) < \delta \quad \text{for every } \Phi_\ell \in B.$$

Since $\overline{D} = X$, there exists an $m_* > m_0$ such that for every $x \in X$, there exists a $x_{i_*} \in D$, $i_* \in \{1, \dots, m_*\}$ with $v(x_{i_*}, x) < \theta$.

So, for every $x \in X$, $m > m_*$ and $n = 1, 2, \dots, m_0$ we have

$$\left| \sum_{k=1}^{k_m} \lambda_k \int_X f_n \circ \Phi_{\ell_k}(y) d\delta_{x_{i_*}} - \sum_{k=1}^{k_m} \lambda_k \int_X f_n \circ \Phi_{\ell_k}(y) d\delta_x \right| < \varepsilon \cdot \|f_n\|$$

and in view of (4), since $i_* \in \{1, \dots, m_*\}$, we have for every $x \in X$, $m > m_*$ and $n = 1, 2, \dots, m_0$

$$\left| \int_X f_n d\mu_m^{\delta_{x_{i_*}}} - \int_X f_n d\rho_m(\delta_x) \right| \leq 2 \cdot \varepsilon \cdot \|f_n\|$$

(note that $\varepsilon_m < \varepsilon$ for $m > m_* > m_0$).

So, for every $x \in X$, $m > m_*$ we have

$$d(\mu_m^{\delta_{x_{i_*}}}, \rho_m(\delta_x)) < 2\varepsilon + \frac{1}{2^{m_0-1}}.$$

Finally, by (6) we have that for every $x \in X$ and $m > m_*$

$$d(\rho_m(\delta_x), \mu) < \left(2\varepsilon_m + \frac{1}{2^{m-1}}\right) + \left(2\varepsilon + \frac{1}{2^{m_0-1}}\right) < 4\varepsilon + 2\varepsilon = 6\varepsilon$$

(note that for $m > m_* > m_0$, $\varepsilon_m < \varepsilon$ and $\frac{1}{2^{m-1}} < \varepsilon$).

Claim 2. $\rho_m(\sigma) \rightarrow \mu$ uniformly for $\sigma \in \left\{ \sum_{k=1}^s \lambda_k \delta_{x_k} : \sum_{k=1}^s \lambda_k = 1, x_k \in D \right\}$.

Indeed, the claim holds from Claim 1, since $\rho_m(\sigma)$ is a convex combination of measures of the form $\rho_m(\delta_x)$, $x \in X$.

Finally, $\rho_m(\sigma) \rightarrow \mu$ uniformly for every $\sigma \in M(X)$, since the set $\left\{ \sum_{k=1}^s \lambda_k \delta_{x_k} : \sum_{k=1}^s \lambda_k = 1, x_k \in D \right\}$ is dense in $M(X)$ by [9, Chapter II, Theorem 6.3]. $\square$

The following lemma is a simplification of [5, Lemma 4.4].

Lemma 4.2. *Let $\rho_m, m \in \mathbb{N}$ a sequence in $\text{conv}(\Theta)$ as in Proposition 4.1, $\nu_m, m \in \mathbb{N}, h_m, m \in \mathbb{N}$ sequences in $M(X)$ and Seq respectively and $f \in C(X)$. Then*

$$\int_X f \circ \Phi_{h_{m_\ell}} d\rho_{m_\ell}(\nu_{m_\ell}) \longrightarrow \int_X f d\mu \quad \text{for } \ell \rightarrow \infty,$$

for some subsequence $m_\ell, \ell \in \mathbb{N}$, of $m \in \mathbb{N}$.

Proof. Since the action of G on X is equicontinuous, the sequence $\Phi_{h_m}, m \in \mathbb{N}$ is equicontinuous for every sequence $h_m, m \in \mathbb{N}$ in Seq . Then $f \circ \Phi_{h_m}, m \in \mathbb{N}$ is equicontinuous, so by Arzela-Ascoli theorem it has a uniformly convergent subsequence

$$f \circ \Phi_{h_{m_\ell}} \xrightarrow{u} \tilde{f} \in C(X).$$

Then for $\varepsilon > 0$ there exists an $\ell_1 \in \mathbb{N}$ such that

$$\|f \circ \Phi_{h_{m_\ell}} - \tilde{f}\|_\infty < \varepsilon \quad \text{for } \ell \geq \ell_1.$$

So

$$\left| \int_X f \circ \Phi_{h_{m_\ell}} d\rho_{m_\ell}(\nu_{m_\ell}) - \int_X \tilde{f} d\rho_{m_\ell}(\nu_{m_\ell}) \right| < \varepsilon \quad \text{for } \ell \geq \ell_1. \quad (7)$$

On the other hand, by Proposition 4.1 there exists an $\ell_2 \in \mathbb{N}$ such that

$$\left| \int_X \tilde{f} d\rho_{m_\ell}(\nu_{m_\ell}) - \int_X \tilde{f} d\mu \right| < \varepsilon \quad \text{for } \ell \geq \ell_2. \quad (8)$$

By (7) and (8) there exists an $\ell_0 \in \mathbb{N}$ so that

$$\left| \int_X f \circ \Phi_{h_{m_\ell}} d\rho_{m_\ell}(\nu_{m_\ell}) - \int_X \tilde{f} d\mu \right| < 2\varepsilon \quad \text{for } \ell > \ell_0.$$

Hence

$$\int_X f \circ \Phi_{h_{m_\ell}} d\rho_{m_\ell}(\nu_{m_\ell}) \longrightarrow \int_X \tilde{f} d\mu \quad \text{for } \ell \rightarrow \infty.$$

Now it suffices to show that $\int_X f d\mu = \int_X \tilde{f} d\mu$.

Indeed, $\int_X f \circ \Phi_{h_{m_\ell}} d\mu = \int_X f d\mu$, since the Φ_r 's, $r \in Seq$ preserve the measure μ and $f \circ \Phi_{h_{m_\ell}} \xrightarrow{u} \tilde{f}$, so $\int_X f d\mu = \int_X \tilde{f} d\mu$. $\square$

Corollary 4.2. *Let ρ_m , $m \in \mathbb{N}$, ν_m , $m \in \mathbb{N}$, h_m , $m \in \mathbb{N}$ sequences as in Lemma 4.2 and $K \subset X$ Jordan measurable, i.e. $\mu(\partial K) = 0$ (∂K the boundary of K) with $\mu(K) > a$, for some $0 < a < 1$. Then there exists an $m_{\ell_0} \in \mathbb{N}$ such that*

$$\int_X \chi_K \circ \Phi_{h_{m_{\ell_0}}} d\rho_{m_{\ell_0}}(\nu_{m_{\ell_0}}) > a.$$

The proof of the corollary is similar to that of [5, Corollary 4.3], so we omit it.

5 Some technical lemmata

In the sequel, we assume the curriculum of notations and definitions of [4, Section 5]. For $A \subseteq \mathbb{Z}$, $pr_A : \mathbb{N}^{\mathbb{Z}} \rightarrow \mathbb{N}^A$ denotes the natural projection and for $k \in \mathbb{N}$, $Z_k := \{-k, \dots, 0, \dots, k\}$.

We recall from [4] and [5] the following lemmata.

Lemma 5.1. *Let $B \subseteq \mathbb{N}^{\mathbb{Z}}$ compact with $\lambda(B) > 0$ and β with $0 < \beta < 1$. Then there exists an $a = (a_{-k}, \dots, a_{-1}, a_0, a_1, \dots, a_k) \in \mathbb{N}^{Z_k}$, for $k \in \mathbb{N}$ such that*

$$\frac{\lambda(pr_{Z_k}^{-1}\{a\} \cap B)}{\lambda(pr_{Z_k}^{-1}\{a\})} > 1 - \beta.$$

Proof. See [4, Lemma 5.1]. $\square$

Lemma 5.2. *Let $F \subseteq \text{Seq}$ finite. Then there exists a β , $0 < \beta < 1$, such that, if $B \subseteq \mathbb{N}^{\mathbb{Z}}$ measurable, with $\lambda(B) > 0$ and $a \in \mathbb{N}^{\mathbb{Z}_k}$ for some $k \in \mathbb{N}$ satisfying*

$$\frac{\lambda(pr_{\mathbb{Z}_k}^{-1}\{a\} \cap B)}{\lambda(pr_{\mathbb{Z}_k}^{-1}\{a\})} > 1 - \beta,$$

then for sufficiently large n ($n \geq n_1$), there exists a $t_n \in \mathbb{N}^{n-2k-1}$ such that

$$\lambda([\tilde{p}r^{-1}\{(a, t_n, z, a)\} \cap T^{n+|z|}(B)] \cap [\tilde{p}r^{-1}\{a\} \cap B]) > 0$$

for all $z \in F$, (where $|z|$ denotes the length of z).

Proof. See [5, Lemma 6.1]. □

The following lemma is highly technical and its meaning will be clear in the proof of Theorem 6.2.

Lemma 5.3. *Let ν be a Borel probability measure on $X \times Y$ singular with respect to $\mu \times \lambda$, such that the projection of ν on Y coincides with λ . Then given $0 < \omega < 1$, $0 < \theta < 1$ and $h : \mathbb{R}^+ \rightarrow \mathbb{R}^+$ a non-decreasing function, there exist Q_k , $k = 1, 2, \dots, s$, $s \in \mathbb{N}$, disjoint compact subsets of X , $K \subseteq X \setminus \bigcup_{k=1}^s Q_k$ compact, and $B \subseteq Y$ compact, with $\lambda(B) > 0$, such that*

$$(i) \quad \mu(K) > 1 - \omega, \quad \mu(\partial K) = 0 \quad (\partial K \text{ the boundary})$$

$$(ii) \quad \text{setting } e := \text{distance} \left(K, \bigcup_{k=1}^s Q_k \right) > 0, \text{ we have}$$

$$\text{diameter}(Q_k) < h(e) \quad \text{for } k = 1, 2, \dots, s$$

$$(iii) \quad \nu_y \left(\bigcup_{k=1}^s Q_k \right) > 1 - \theta, \quad \text{for } y \in B$$

$$(iv) \quad |\nu_y(Q_k) - \nu_{y'}(Q_k)| < \frac{\theta}{s} \quad \text{for every } y, y' \in B, \quad k = 1, 2, \dots, s$$

(where ν_y denotes the conditional measure induced by ν on the fiber $X \times \{y\}$).

Proof. See [4, Lemma 6.1]. □

Note. Although the Φ 's in [4] are commutative, this is not used in the proof of [4, Lemma 6.1].

Under the assumptions of Lemma 5.3, we have the following

Corollary 5.1. *Let $y_0 \in B$, $B' \subset B$ measurable, with $\lambda(B') > 0$ and $\mathcal{P} \subset \{1, 2, \dots, s\}$, such that*

$$\sum_{k \in \mathcal{P}} \nu_{y_0}(Q_k) > 1 - \varepsilon, \text{ for } 0 < \varepsilon < 1.$$

Then

$$\nu\left(\left(\bigcup_{k \in \mathcal{P}} \overline{Q_k}\right) \times B'\right) > ((1 - \varepsilon) - \theta) \cdot \lambda(B').$$

Proof. See [5, Corollary 5.1]. □

6 The proof of Theorem 2.1

The proof of Theorem 2.1 will be given in two major steps. First, we shall prove that if τ is absolutely continuous with respect to $\mu \times \lambda$ then τ coincides with $\mu \times \lambda$. Second, we shall prove that τ has a trivial singular part with respect to $\mu \times \lambda$. These two steps are described in Theorems 6.1 and 6.2, respectively.

We have

Theorem 6.1. *The measure $\mu \times \lambda$ is the unique Borel probability measure on $X \times Y$, invariant under Ψ and absolutely continuous with respect to $\mu \times \lambda$.*

Proof. This follows from the ergodicity of the skew product Ψ , see the random ergodic theorem in [10]. □

Remark. Note that the use of the random ergodic theorem of Ryll-Nardzewski

(see [10]) gives immediately Theorem 6.1, so we can omit the lengthy proof of the “first step” that appears in [4, Proposition 5.1] and [5, Theorem 6.1].

The proof of the following theorem is an amalgamation of the proofs of [4, Theorem 7.1] and [5, Theorem 7.1].

Theorem 6.2. *Let ν be a Borel probability measure on $X \times Y$ singular with respect to $\mu \times \lambda$, such that the projection of ν on Y coincides with λ . Then ν is not invariant under Ψ .*

Proof. Suppose that the conclusion of the theorem does not hold i.e. ν is invariant for Ψ .

Since the semigroup $\mathcal{H}$ generated by $\Phi_1, \dots, \Phi_n, \dots$ acts equicontinuously on X (by Corollary 4.1), if ρ denotes the metric on X , then clearly there exists a non-decreasing $h : \mathbb{R}^+ \rightarrow \mathbb{R}^+$, such that for every $f \in \mathcal{H}$ and $x, y \in X$ with $\rho(x, y) < h(\delta)$ ($\delta > 0$), then $\rho(f(x), f(y)) < \delta$. Now given $0 < \omega < \frac{1}{100}$, $0 < \theta < \frac{1}{100}$ and h as above, by Lemma 5.3 there exist Q_k , $k = 1, \dots, s$, disjoint compact subsets of X , $K \subseteq X \setminus \bigcup_{k=1}^s Q_k$ compact and $B_1 \subseteq Y := \tilde{\mathbb{N}}^{\mathbb{Z}}$ compact with $\lambda(B_1) > 0$ satisfying conditions (i), (ii), (iii), (iv) of the lemma, (with B_1 in place of B).

Let $B'_1 := B_1 \cap \mathbb{N}^{\mathbb{Z}}$. Then $\lambda(B'_1) = \lambda(B_1) > 0$ and by the regularity of λ , there exists some compact $B \subseteq B'_1$, such that $\lambda(B) > 0$. The set B satisfies the conditions of Lemma 5.3

We consider ρ_m , $m \in \mathbb{N}$ a sequence in $\text{conv}(\Theta)$ as in Proposition 4.1. Since $\rho_m \in \text{conv}(\Theta)$, there exist a finite $F_m \subset \text{Seq}$ and $\theta_z(m) > 0$ for $z \in F_m$, such that $\sum_{z \in F_m} \theta_z(m) = 1$ and $\rho_m = \sum_{z \in F_m} \theta_z(m) \varphi_z$.

By Lemma 5.2 for each F_m , ($m \in \mathbb{N}$) there exists a β_m , $0 < \beta_m < 1$, satisfying the conclusion of that lemma.

Applying Lemma 5.1 repeatedly, we find for each couple

$$B, \beta_m \quad m = 1, 2, \dots$$

a $k_m \in \mathbb{N}$ and an $a^{(m)} = (a_{-k_m}^{(m)}, \dots, a_0^{(m)}, \dots, a_{k_m}^{(m)}) \in \mathbb{N}^{\mathbb{Z}_{k_m}}$ satisfying

$$\frac{\lambda(B \cap pr_{\mathbb{Z}_{k_m}}^{-1} \{a^{(m)}\})}{\lambda(pr_{\mathbb{Z}_{k_m}}^{-1} \{a^{(m)}\})} > 1 - \beta_m \quad (9)$$

for $m = 1, 2, \dots$.

Next, applying Lemma 5.2 repeatedly, taking in view of (9), we find for each quadruple

$$F_m, \beta_m, B, a^{(m)} \in \mathbb{N}^{\mathbb{Z}_{k_m}} \quad \text{for some } k_m \in \mathbb{N}, \quad m = 1, 2, \dots,$$

an $n_m \in \mathbb{N}$ and a $t_{n_m} \in \mathbb{N}^{n_m - 2k_m - 1}$ such that, setting $t_{n_m} = t_m$ for brevity in the notation,

$$\lambda([\tilde{p}r^{-1}\{a^{(m)}, t_m, z, a^{(m)}\} \cap T^{n_m+|z|}(B)] \cap [\tilde{p}r^{-1}\{a^{(m)}\} \cap B]) > 0, \quad (10)$$

for all $z \in F_m$.

In the sequel we fix some $y_0 \in B$ and set

$$\gamma_k := \frac{\nu_{y_0}(Q_k)}{\nu_{y_0}\left(\bigcup_{i=1}^s Q_i\right)}, \quad k = 1, 2, \dots, s.$$

We fix $x_k \in Q_k$, $k = 1, 2, \dots, s$ and consider the probability measure

$$\tau := \sum_{k=1}^s \gamma_k \delta_{x_k}, \quad (\delta_{x_k} \text{ the Dirac measure}).$$

At the present situation, we can apply Corollary 4.2 for the sequences ρ_m , $m \in \mathbb{N}$ (previously considered),

$$h_m := (a_{-k_m}^{(m)}, \dots, a_{-1}^{(m)}, a_0^{(m)}), \quad m \in \mathbb{N}, \quad \nu_m := \varphi_{(a_+^{(m)}, t_m)} \tau, \quad m \in \mathbb{N}$$

and K , (where $a_+^{(m)} = (a_1^{(m)}, \dots, a_{k_m}^{(m)})$ and $a_-^{(m)} = (a_{-k_m}^{(m)}, \dots, a_0^{(m)}) (= h_m)$) and find an m_{ℓ_0} such that, setting $m_{\ell_0} = m_0$ for brevity in the notation

$$\int_X \chi_K \circ \Phi_{a_-^{(m_0)}} d\rho_{m_0}(\nu_{m_0}) > 1 - \omega.$$

Since ρ_{m_0} is a convex combination, there exists a $z_{m_0}^* \in F_{m_0}$ such that

$$\int_X \chi_K \circ \Phi_{a_-^{(m_0)}} d\varphi_{z_{m_0}^*}(\nu_{m_0}) > 1 - \omega,$$

i.e. by the form of ν_{m_0}

$$\int_X \chi_K \circ \Phi_{(a_+^{(m_0)}, t_{m_0}, z_{m_0}^*, a_-^{(m_0)})} d\tau > 1 - \omega. \quad (11)$$

We set

$$\xi_k := \Phi_{(a_+^{(m_0)}, t_{m_0}, z_{m_0}^*, a_-^{(m_0)})}(x_k), \quad k = 1, \dots, s$$

and since

$$\varphi_{(a_+^{(m_0)}, t_{m_0}, z_{m_0}^*, a_-^{(m_0)})} \left(\sum_{k=1}^s \gamma_k \delta_{x_k} \right) = \sum_{k=1}^s \gamma_k \delta_{\xi_k}$$

setting $\mathcal{P} := \{k \in \{1, 2, \dots, s\} \mid \xi_k \in K\}$, by (11) we have

$$\sum_{k \in \mathcal{P}} \gamma_k > 1 - \omega.$$

So, by the definition of the γ_k 's

$$\sum_{k \in \mathcal{P}} \nu_{y_0}(Q_k) > (1 - \omega) \cdot \nu_{y_0} \left(\bigcup_{i=1}^s Q_i \right)$$

and since by (iii) of Lemma 5.3 $\nu_{y_0} \left(\bigcup_{i=1}^s Q_i \right) > 1 - \theta$ we have

$$\sum_{k \in \mathcal{P}} \nu_{y_0}(Q_k) > (1 - \omega)(1 - \theta). \quad (12)$$

Claim. $\left(\Phi_{(a_+^{(m_0)}, t_{m_0}, z_{m_0}^*, a_-^{(m_0)})} \left(\bigcup_{k \in \mathcal{P}} \overline{Q_k} \right) \right) \cap \left(\bigcup_{k=1}^s Q_k \right) = \emptyset.$

Indeed, by (ii) of Lemma 5.3, $\text{diameter}(\overline{Q_k}) = \text{diameter}(Q_k) < h(e)$, for $k = 1, 2, \dots, s$, where $e := \text{distance} \left(K, \bigcup_{k=1}^s Q_k \right)$, so we have

$$\text{diameter}(\Phi_{(a_+^{(m_0)}, t_{m_0}, z_{m_0}^*, a_-^{(m_0)})}(\overline{Q_k})) < e, \quad \text{for } k = 1, 2, \dots, s.$$

On the other hand by the definition of $\mathcal{P}$, we have $\xi_k := \Phi_{(a_+^{(m_0)}, t_{m_0}, z_{m_0}^*, a_-^{(m_0)})}(x_k) \in K$, for $k \in \mathcal{P}$, where $x_k \in Q_k$. So for $k \in \mathcal{P}$

$$(\Phi_{(a_+^{(m_0)}, t_{m_0}, z_{m_0}^*, a_-^{(m_0)})}(\overline{Q_k})) \cap \left(\bigcup_{k=1}^s Q_k \right) = \emptyset$$

i.e. the claim.

Next, we set

$$W^* := [\tilde{p}r^{-1}\{(a^{(m_0)}, t_{m_0}, z_{m_0}^*, a^{(m_0)}) \cap T^{n_{m_0}+|z_{m_0}^*|}(B)\}] \cap [\tilde{p}r^{-1}\{a\} \cap B].$$

(where $|z_{m_0}^*|$ denotes the length of $z_{m_0}^*$)

By (10) we have $\lambda(W^*) > 0$. Clearly, $T^{-(n_{m_0}+|z_{m_0}^*|)}(W^*) \subseteq B$, so by (12) and Corollary 5.1 we have

$$\begin{aligned} \nu\left(\left(\bigcup_{k \in \mathcal{P}} \overline{Q_k}\right) \times T^{-(n_{m_0}+|z_{m_0}^*|)}(W^*)\right) &> ((1-\omega)(1-\theta) - \theta) \cdot \lambda(T^{-(n_{m_0}+|z_{m_0}^*|)}(W^*)) \\ &= ((1-\omega)(1-\theta) - \theta) \cdot \lambda(W^*). \end{aligned} \quad (13)$$

Clearly, by the form of W^* we have

$$\Psi^{n_{m_0}+|z_{m_0}^*|}\left(\left(\bigcup_{k \in \mathcal{P}} \overline{Q_k}\right) \times T^{-(n_{m_0}+|z_{m_0}^*|)}(W^*)\right) = (\Phi_{(a_+^{(m_0)}, t_{m_0}, z_{m_0}^*, a_-^{(m_0)})}\left(\bigcup_{k \in \mathcal{P}} \overline{Q_k}\right)) \times W^* \quad (14)$$

which is measurable, since $\overline{Q_k}$ are compact sets.

By the invariance of ν under Ψ and (13) we have

$$\begin{aligned} \nu\left[\Psi^{n_{m_0}+|z_{m_0}^*|}\left(\left(\bigcup_{k \in \mathcal{P}} \overline{Q_k}\right) \times T^{-(n_{m_0}+|z_{m_0}^*|)}(W^*)\right)\right] &> \nu\left[\left(\bigcup_{k \in \mathcal{P}} \overline{Q_k}\right) \times T^{-(n_{m_0}+|z_{m_0}^*|)}(W^*)\right] \\ &> ((1-\omega)(1-\theta) - \theta) \cdot \lambda(W^*). \end{aligned} \quad (15)$$

By (14) and (15) we have

$$\nu\left[\left(\Phi_{(a_+^{(m_0)}, t_{m_0}, z_{m_0}^*, a_-^{(m_0)})}\left(\bigcup_{k \in \mathcal{P}} \overline{Q_k}\right)\right) \times W^*\right] > ((1-\omega)(1-\theta) - \theta) \cdot \lambda(W^*). \quad (16)$$

On the other hand, since clearly $W^* \subseteq B$, by (iii) of Lemma 5.3 we have $\nu_y\left(\bigcup_{k=1}^s Q_k\right) > 1 - \theta$, for every $y \in W^*$ and intergrating the above inequality over W^* , we have

$$\nu\left(\left(\bigcup_{k=1}^s Q_k\right) \times W^*\right) > (1 - \theta) \cdot \lambda(W^*). \quad (17)$$

Finally, (16), (17) and the claim give

$$\nu(X \times W^*) > \frac{3}{2} \cdot \lambda(W^*)$$

which obviously contradicts the fact that the projection of ν on Y coincides with λ . $\square$

Finally, combining Theorems 6.1 and 6.2, we can conclude the proof of Theorem 2.1. For more details, see [5, Section 8].

Acknowledgements. We would like to express our gratitude to Professor Constantinos Gryllakis for his guidance during the preparation of this manuscript.
